DIRECTIONS IN $AG(2, p^2)$

ANDRÁS GÁCS, LÁSZLÓ LOVÁSZ, AND TAMÁS SZŐNYI

ABSTRACT. In this paper we prove that if q is the square of a prime and U is a set of q points determining at least $\frac{q+3}{2}$ directions, then either U is the graph of the function $x^{\frac{q+1}{2}}$ or it determines at least $\frac{q+p}{2}+1$ directions. This is sharp, the example is due to Polverino, Szőnyi and Weiner [10]. Our method combines the lacunary polynomial and the double power sum approach.

1. INTRODUCTION

Throughout this paper $U = \{(a_i, b_i) : i = 1, \dots, q\}$ will denote a q-element point set in $AG(2, q)$, the Desarguesian affine plane of order q. We write $D = \{\frac{b_i - b_j}{a_i - a_j} : i \neq j\}$ and call elements of this set *the directions determined by* U. This is a subset of $GF(q) \cup \{\infty\}$ and consists of slopes of lines joining two points of U. Finally, let $N = |D|$, the number of determined directions.

The problem of determining the possible values of N and characterizing the corresponding point sets has received a lot of attention in the last years. For motivation and the history of the problem we refer to [4] and [3]. Here we summarize some known results.

RESULT 1.1. *(Rédei* [11]*; Ball, Blokhuis Brouwer, Storme, Szőnyi* [4] *and Ball* [1]*) Let $q = p^h$ and let $s = p^e$ be maximal with the property that any line containing at least two points of U meets U in a multiple of s points. Then one of the following holds:*

(i) *$s = 1$ and $\frac{q+3}{2} \leq N \leq q + 1$;*
(ii) *$GF(s)$ is a subfield of $GF(q)$ and $1 + q/s \leq N \leq (q - 1)/(s - 1)$;*
(iii) *$s = q$ and $N = 1$.*

Moreover, if $s > 2$, then U can be regarded as a coset of a vector space over $GF(s)$.

This result solves the problem entirely for the case $N < \frac{q+3}{2}$. It was first proved in [4] with some exceptions for the characteristic 2 and 3 cases. Recently S. Ball [1] found an easier proof which also handles the missing cases.

For the case $N \geq \frac{q+3}{2}$ there have been results only when q is a prime:

RESULT 1.2. (i) *(Lovász and Schrijver* [9]*) If q is a prime, then the only sets determining $\frac{q+3}{2}$ directions are the affine equivalents of the graph of the function $x^{\frac{q+1}{2}}$.*
(ii) *(Gács* [7]*) If q is prime and $N > \frac{q+3}{2}$, then $N \geq [2\frac{q-1}{3} + 1]$.*

The first author was supported by Magyary and Bolyai grant and OTKA grant F 043772. The first and third authors were supported by OTKA grants T 043758 and T 049662, and TÉT grant E16/04. All authors were supported by OTKA grant T 067867.

Let us mention that for the case q is a prime Result 1.1 gives that N is at least $\frac{q+3}{2}$, unless $N = 1$ (that is U is a line). This was already observed by Rédei and Megyesi, see [11]. The graph of $x^{\frac{q+1}{2}}$ determines $\frac{q+3}{2}$ directions for any odd prime power q, showing that the bound in Result 1.1 (i) is sharp.

In this paper we consider the next case, that is, when q is the square of a prime. We prove an analogous result to the two statements of Result 1.2:

THEOREM 1.3. *Suppose that $q = p^2$, where p is prime and U is a set of q points in $AG(2, q)$ determining at least $\frac{q+3}{2}$ directions. Then either U is affinely equivalent to the graph of $x^{\frac{q+1}{2}}$, or the number of directions is at least $\frac{q+p}{2} + 1$.*

The bound is sharp: Polverino, Szőnyi and Weiner [10] constructed an example determining $\frac{q+\sqrt{q}}{2} + 1$ directions when q is a square. We conjecture that for any square prime power, this should be the next possible value for N, that is, $\frac{q+3}{2} < N < \frac{q+\sqrt{q}}{2} + 1$ cannot happen for q square.

We continue with some preliminary remarks on polynomials over finite fields and Lucas' theorem. For proofs, see [8].

When U does not determine all directions, that is, $N < q + 1$, one can find a suitable transformation (not affecting N) to achieve that $U = \{(x, f(x)) : x \in GF(q)\}$ for some function f. After this we have another form for D; namely, it is easy to see that D consists of those $c \in GF(q)$ for which $f(x) - cx$ is not bijective.

Over the finite field $GF(q)$ any function can be written as a polynomial of degree at most $q - 1$. This is called the *reduced form* of f. For any $f(x) = c_{q-1}x^{q-1} + \cdots + c_1x + c_0$, $\sum_{x \in GF(q)} f(x) = -c_{q-1}$. f is called a *permutation polynomial* if it is bijective as a function. For such polynomials we have $\sum_{x \in GF(q)} f(x)^k = 0$ for any $1 \le k \le q-2$; this is equivalent to saying that in the reduced form of $f(x)^k$ the coefficient of x^{q-1} is zero.

Lucas' theorem tells how binomial coefficients behave modulo a prime p. Let the p-adic expansion of n and k be $n = \sum_{i=1}^{r} n_i p^{i-1}$ and $k = \sum_{i=1}^{r} k_i p^{i-1}$, respectively. Then $\binom{n}{k} \equiv \binom{n_1}{k_1} \cdots \binom{n_r}{k_r}$ modulo p.

Finally, we show how the direction problem is connected to blocking sets in $PG(2, q)$. A *blocking set* B in the projective plane $PG(2, q)$ is a set of points meeting every line. B is called *non-trivial*, if it contains no line and *minimal*, if it does not contain properly a blocking set.

If U is a set of q points in $AG(2, q)$ and D is the set of determined directions, then embedding $AG(2, q)$ into $PG(2, q)$ and adding to U the infinite points corresponding to elements in D, we get a blocking set B of the projective plane. It contains a line if and only if either U was an affine line or U determined every direction. B has the property, that there is a line (the line at infinity) missing exactly q points of B. It is easy to see that this property characterizes minimal blocking sets arising from the above construction; they are called blocking sets of *Rédei type*.

In the next section we deal with blocking sets in general. After some easy observations we will end up in a result about Rédei type blocking sets (Proposition 2.4), which will be used in the proof of Theorem 1.3.

We will consider $PG(2,q)$ as $AG(2,q)$ extended by the line at infinity, l_∞. The infinite point of lines with slope c will be denoted by (c), the infinite point of the vertical lines will be denoted by (∞).

2. Blocking sets

Suppose that B is a blocking set in $PG(2,q)$ with $|B| < 2q-1$ and $(\infty) \notin B$. Write $U = B \setminus l_\infty = \{(a_i,b_i) : i = 1,\cdots,k\}$ and $D = B \cap l_\infty = \{(y_i) : i = 1,\cdots,N\}$. The *Rédei polynomial of* U is defined as

$$H(X,Y) = \prod_{i=1}^{k}(X + a_iY + b_i).$$

We will often use the Rédei polynomial of B also, which is

$$H^*(X,Y) = \prod_{i=1}^{N}(Y + y_i)H(X,Y).$$

Finally, the *homogeneous Rédei polynomial of* B is defined as

$$R(X,Y,Z) = \prod_{i=1}^{N}(Y + y_iZ)\prod_{i=1}^{k}(X + a_iY + b_iZ).$$

Note that R is the homogenization of H^*.

Lemma 2.1. (i) *There exist polynomials f_1 and f_2 of degree at most $|B|-q$ such that $H^*(X,Y) = (X^q - X)f_1(X,Y) + (Y^q - Y)f_2(X,Y)$ holds;*
(ii) *there exist homogeneous polynomials f,g,h of degree $|B|-q$ such that $R(X,Y,Z) = X^qf + Y^qg + Z^qh$ holds;*
(iii) *$Xf + Yg + Zh = 0$ for the polynomials found in (ii);*
(iv) *for any $(x,y,z) \in GF(q)^3\setminus(0,0,0)$, $f(x,y,z) = -R'_X(x,y,z)$, $g(x,y,z) = -R'_Y(x,y,z)$, $h(x,y,z) = -R'_Z(x,y,z)$ holds for the polynomials found in (ii).*

Proof (i) is well-known, see Blokhuis [2]. For the homogenization of H^* it gives that it is of the form $R = X^qf_1^* + Y^qf_2^* - Z^{q-1}(Xf_1^* + Yf_2^*)$. Hence the polynomials $f = f_1^*, g = f_2^*$ and $h = -\frac{1}{Z}(Xf_1^* + Yf_2^*)$ will be appropriate for (ii) and (iii), provided that we can prove that $Z|Xf_1^* + Yf_2^*$. Consider the terms of R not containing Z. These are $Y^N\prod_i(X + a_iY)$. Since $(\infty) \notin B$, each element of $GF(q)$ occurs at least once as an a_i. Hence the terms we are looking for can be written as $X^MY^N(X^{q-1} - Y^{q-1})s(X,Y)$ $(M,N \geq 1)$. They all come from $X^qf_1^* + Y^qf_2^*$, so we have to find out the terms containing X^q and Y^q, which are $X^qX^{M-1}Y^Ns(X,Y)$ and $-Y^qX^MY^{N-1}s(X,Y)$. Hence the terms in $Xf_1^* + Yf_2^*$ not containing Z are $XX^{M-1}Y^Ns(X,Y) - YX^MY^{N-1}s(X,Y) = 0$.

(iv) easily follows from (iii) and the derivative of (ii). □

The following lemma gives an easy consequence of Lemma 2.1.

Lemma 2.2. *Suppose that the line $l : aX + bY + cZ = 0$ is a 1-secant to B. Then the unique intersection point of l and B is $(f(a,b,c), g(a,b,c), h(a,b,c))$.*

Proof The point $(f(a,b,c), g(a,b,c), h(a,b,c))$ is on the line in question by Lemma 2.1 (iii). At this stage it is more convenient to not distinguish the affine and infinite points of B, so write $B = \{(u_i, v_i, w_i) : i = 1, ..., k+N\}$, hence $R(X,Y,Z) = \prod_{i=1}^{k+N}(u_iX + v_iY + w_iZ)$. Differentiate R with respect to X to find $R'_X(X,Y,Z) = \sum_i u_i \prod_{j\neq i}(u_jX + v_jY + w_jZ)$. If we substitute $X = a$, $Y = b$ and $Z = c$, then all products in the sum will be zero, except for the case when (u_i, v_i, w_i) is the intersection point, hence $R'_X(a,b,c) = u_i \prod_{j\neq i}(u_ja+v_jb+w_jc)$ (for this i). Similarly we have $R'_Y(a,b,c) = v_i \prod_{j\neq i}(u_ja+v_jb+w_jc)$ and $R'_Z(a,b,c) = w_i \prod_{j\neq i}(u_ja + v_jb + w_jc)$. Since the line $aX + bY + cZ = 0$ is a 1-secant to B, this product is non-zero. By Lemma 2.1 (iv), we are done. □

Note that when the line $aX + bY + cZ = 0$ meets B in more then one point, then $f(a,b,c) = g(a,b,c) = h(a,b,c) = 0$.

Now we suppose that B is of Rédei type. Hence $k = q$ and $D = \{(y_i) : i = 1, \cdots, N\}$ is the set of determined directions of the affine set $U = \{(a_i, b_i) : i = 1, \ldots, q\}$.

Note that in this case we have $f(X,Y,Z) = \prod_{i=1}^{N}(Y + y_iZ)$ in Lemma 2.1.

Definition 2.3. *The index I of B is defined so that the X-degree of $Y^qg + Z^qh$ is $q - I$.*

From Lemma 2.1 (iii) we see that $q - I$ is also the X-degree of g and h (unless one of them is 1 and the other is 0). Note that considering H as a polynomial in X (with coefficient polynomials in Y), X^{q-I} is the first term after X^q with non-vanishing coefficient polynomial.

Proposition 2.4. (i) *If the infinite point (y) does not belong to B (that is, (y) is not a determined direction), then the affine part of B is equivalent to $\{(\frac{1}{c}g(t,y,-1), t) : t \in GF(q)\}$; where $c \neq 0$ depends on y.*

(ii) *If $q - N > N + I - q$, then by a suitable linear transformation we can suppose that the affine part of B is the graph of a polynomial of degree $q - I$.*

Proof If (y) is not determined, then all affine lines through it are 1-secants, hence by calculating the intersections of B and these lines, we can determine the q affine points.

The lines in question have equation $tX_0 + yX_1 - X_2 = 0$, so by Lemma 2.1, we find that the affine part of B is

$$\{(f(t,y,-1), g(t,y,-1), h(t,y,-1)) : t \in GF(q)\}.$$

We know that $f(t,y,-1) = \prod(y - y_i)$, and from Lemma 2.1 (iii) we have $yg(t,y,-1) - h(t,y,-1) = -\prod(y - y_i)t$. Note that $c := \prod(y - y_i)$ is a constant, hence after the transformation $X'_2 = X_2 - yX_1$ we find the form claimed in (i).

By the definition of I, after (i) we only need that there is a suitable non-determined direction (y), for which the degree of $g(X,y,-1)$ is the same as the X-degree of g. We have $q-N$ choices for y. The coefficient of X^{q-I} in $g(X,Y,Z)$ is a homogeneous polynomial $g_0(Y,Z)$ of degree $|B| - q - (q - I) = N + I - q$. If this is smaller than $q - N$, then from the fact that g_0 is not identically zero, we should have an appropriate y. □

Remark 2.5. Similar ideas and some of the results were used by Sziklai to prove results about small blocking sets, see [12].

3. Results about directions for general q

In the spirit of the introduction, from now on $U = \{(x, f(x)) : x \in GF(q)\}$, $D = \{\frac{f(x)-f(y)}{x-y} : x \neq y\} = \{c \in GF(q) : f(x) - cx \text{ is not a perm. pol.}\}$ and $N(f) = |D|$. Here $f(x) = c_n x^n + \cdots + c_0$ with $\deg(f) = n \leq q-1$. In this section we introduce two more parameters depending on f and relate it to $N(f)$.

By the remarks at the end of the introduction, $U \cup D$ is a blocking set of Rédei type. In this case the Rédei polynomial is

$$H(X,Y) = \prod_{t \in GF(q)} (X + tY + f(t)).$$

Expanding H in powers of X, we have

$$H(X,Y) = X^q + h_1(Y)X^{q-1} + ... + h_q(Y). \tag{1}$$

Write $h_i(Y) = \sum_j \sigma_{i-j,j} Y^j$. Note that h_i is the i-th elementary symmetric polynomial of the multiset $\{Yt + f(t) : t \in GF(q)\}$. It is easy to see that $\sigma_{0,i}$, that is, the coefficient of Y^i in h_i, is the i-th elementary symmetric polynomial of the set $GF(q)$. This is zero for $1 \leq i \leq q-2$, so for these i-s, $\deg(h_i) \leq i-1$.

In general for $(a,b) \neq (0,0)$ we have the following for $\sigma_{a,b}$ (the coefficient of Y^a in h_{a+b}, that is, the coefficient of $X^{q-a-b}Y^a$ in $H(X,Y)$):

$$\sigma_{a,b} = \sum_{t_1,...,t_a,u_1,...,u_b} t_1 \cdots t_a \cdot f(u_1) \cdots f(u_b),$$

where the sum is over all choices of $t_1, ..., t_a, u_1, ..., u_b$ all different. For $a = b = 0$, we have $\sigma_{0,0} = 1$.

The use of $H(X,Y)$ is that it translates intersection properties of U to algebraic ones. This was used in all proofs mentioned in the Introduction and in Section 2.

Lemma 3.1. *Fixing a $Y = y_0$ and considering $H(X, y_0)$ as a polynomial in X, the multiplicities of its roots are the same as a multiset as the intersection sizes of lines through the infinite point $(-y_0)$ with U.*

Proof See Rédei [11]. □

We introduce another series of polynomials:

$$g_k(c) := \sum_{t \in GF(q)} (f(t) + ct)^k = \sum_{i=0}^{k} \binom{k}{i} \pi_{i,k-i} c^i, \tag{2}$$

where $\pi_{a,b} = \sum_{t \in GF(q)} t^a f(t)^b$. Define $\pi_{0,0}$ to be 1. Note that the g_k-s are the power sums of the multiset $\{f(t) + ct : t \in GF(q)\}$.

The two parameters (depending on the reduced polynomial f) to be introduced are the following.

Definition 3.2. *The first index of f, $I_1(f)$ is defined to be the smallest positive integer k for which the polynomial h_k defined by (1) is not identically zero.*

The second index of f, $I_2(f)$ is defined to be the smallest positive integer k for which the polynomial g_k defined by (2) is not identically zero.

Note that $I_1(f)$ coincides with the index (of the blocking set) defined in the previous section. The reason for not using the same notation is that we want to stress that I is a parameter of the blocking set B, while I_1 (and I_2) are parameters of the affine part U of the blocking set.

The proof in [4] and in [1] use lacunary polynomials arising from $H(X,Y)$, this means the consideration of the parameter $I_1(f)$. On the other hand, [9] and [7] use double power sums in the proof, this is the consideration of the parameter $I_2(f)$.

In this paper we use both parameters, it seems that this might be the way of attacking the $N \geq \frac{q+3}{2}$ case. Next we relate I_1, I_2 and N to each other. Most of these observations are at least implicitly stated in one of the above mentioned papers. The first part was also observed by Evans, Greene and Niederreiter [6].

LEMMA 3.3. (i) *If $I_1(f) \geq \frac{q+1}{2}$, then $N(f) \leq \frac{q-1}{p-1}$;*

(ii) *if $N(f) > 1$, then $q + 1 - N(f) \leq I_1(f) \leq I_2(f)$, with $I_1(f) = I_2(f)$ if and only if p does not divide $I_1(f)$.*

Proof For (i) we refer to [4]. This is the first easy step of the proof which was already found by Rédei [11].

$I_1(f) \leq I_2(f)$ and the characterization of the case of equality is a consequence of the Newton formulas relating power sums and elementary symmetric polynomials.

For $q+1-N(f) \leq I_1(f)$ note that fixing any $-y \notin D$ we have $H(X,y) = X^q - X$, hence for these y-s $h_1(y) = \cdots = h_{q-2}(y) = 0$. For $h_1, \ldots, h_{q-N(f)}$ these are more roots than their degrees, so these h_i-s are identically zero. □

COROLLARY 3.4. *Suppose q is odd. If $\frac{q+3}{2} \leq N(f) \leq \frac{q+p}{2}$, then $I_1(f) = I_2(f)$.*

Proof From Lemma 3.3 we deduce $\frac{q-p}{2} + 1 \leq I_1(f) \leq \frac{q-1}{2}$, so I_1 cannot be divisible by p. The same lemma gives $I_1 = I_2$. □

LEMMA 3.5. *Suppose $N(f) < 3q/4$ and $I_1(f) \leq \frac{q-1}{2}$. Then one can make a linear transformation for the graph of f to find the graph of another polynomial f_1 with $\deg(f_1) = q - I_1(f_1) = q - I_1(f)$.*

Proof This is a consequence of 2.4 (ii). The conditions are easily seen to be satisfied, so after transformation, we can find the desired f_1. Since this is in fact a transformation of the blocking set that fixes the Rédei line, $N(f_1) = N(f)$ and by the original definition of I, we see that $I_1(f) = I_1(f_1)$. □

The following lemma gives a relation between the above defined $\sigma_{k,l}$-s and $\pi_{k,l}$-s. It can be considered as a generalization of the Newton-Girard formulas relating elementary symmetric polynomials to power sums.

LEMMA 3.6. *Fix two positive integers k and l. The following formula holds:*

$$\sum_{r=0}^{k} \sum_{s=0}^{l} f(r,s) \pi_{r,s} \sigma_{k-r,l-s} = 0,$$

where the function $f(r,s)$ is defined as follows: fix two field-elements a and b, then $f(0,0) := ak + bl$; while for $(r,s) \neq (0,0)$

$$f(r,s) := (-1)^{r+s}\left(\binom{r+s-1}{s}a + \binom{r+s-1}{r}b\right).$$

(That is, we get a formula for every choice of a and b.)

Proof It is easy to see that after multiplication on the left hand side we have monomials of the form $t^r f(t)^s t_1 \cdots t_{k-r} f(u_1) \cdots f(u_{l-s})$, where $t, t_1, ..., u_{l-s}$ are different field elements and $0 \leq r \leq k$, $0 \leq s \leq l$.

If r and s are both positive, then we can get such a term from three summands: $\pi_{r,s}\sigma_{k-r,l-s}$, $\pi_{r-1,s}\sigma_{k+1-r,l-s}$ and $\pi_{r,s-1}\sigma_{k-r,l+1-s}$. Hence the coefficient of such a monomial is $f(r,s) + f(r,s-1) + f(r-1,s) = 0$.

If $r = 0$, $s > 1$, then there are two summands giving the monomial in question: $\pi_{0,s}\sigma_{k,l-s}$ and $\pi_{0,s-1}\sigma_{k,l+1-s}$, so the coefficient is $f(0,s) + f(0,s-1) = 0$. The $s = 0$, $r > 1$ case is similar.

The $\{r,s\} = \{0\}$ and $\{r,s\} = \{0,1\}$ cases are the same, so what is left is to show that monomials of the form $t_1 \cdots t_k f(u_1) \cdots f(u_k)$ also have zero coefficient. There are three summands giving them: $\pi_{0,0}\sigma_{k,l}$ (one time), $\pi_{1,0}\sigma_{k-1,l}$ (k times) and $\pi_{0,1}\sigma_{k,l-1}$ (l times). Hence the coefficient in question is $f(0,0) + lf(0,1) + kf(1,0) = 0$. □

We will use two corollaries of this lemma. The first one was noticed by Chou [5].

COROLLARY 3.7. (i) $\deg(f) \leq q - I_1(f)$;

(ii) *in the reduced form of f^2 the only non-zero terms of degree higher than $q+1-I_1(f)$ can be those of degree divisible by p.*

Proof (i) By the definition of I_1, we know that $\sigma_{k,l} = 0$ for every $0 < k + l < I_1(f)$. We use the formula of Lemma 3.6 with $l = 1$, $a = 0$ and $b = 1$. It gives $(-1)^{k+1}\binom{k}{k}\pi_{k,1} = 0$ for all $k \leq I_1(f) - 2$, which means that the coefficients of $x^{q-1}, x^{q-2}, ..., x^{q-I_1(f)+1}$ are zero in f.

(ii) Similarly to (i), now we use the formula with $l = 2$, $a = 0$, $b = 1$ to find $(-1)^{k+2}\binom{k+1}{k}\pi_{k,2} = 0$ for all $k \leq I_1(f) - 3$. This gives that in the reduced form of $f^2 x^k$, the coefficient of x^{q-1} is zero, unless $p|k+1$; this is exactly what we wanted.

□

In the next theorem, we summarize what we have so far.

THEOREM 3.8. *Suppose U is a set of q points in $AG(2,q)$ determining $N \leq \frac{q+p}{2}$ directions, where q is a proper power of the odd prime p. Then either $N \leq \frac{q+1}{2}$ and we know all such examples from the classification* [1],[4]*, or U is affinely equivalent to the graph of a polynomial f with $I_1(f) = I_2(f) = \frac{q-1}{2}$ and $\deg(f) = \frac{q+1}{2}$.*

Proof The previous lemmas together yield that after transformation, U is the graph of a polynomial $f(x) = x^n + ... + c_2x^2 + c_1x + c_0$ with $\frac{q-p}{2} + 1 \leq I_1(f) = I_2(f) = q + 1 - n \leq \frac{q+1}{2}$. All we need is that $n = \frac{q+1}{2}$.

Write $n = \frac{q-1}{2} + r$ with $1 \leq r \leq \frac{p-1}{2}$. Consider the reduced form of f^p. The term x^n will give $x^{(q-1)/2+rp}$ (after reduction). Hence $\sum x^{(q-1)/2-rp} f(x)^p \neq 0$. Since $\binom{(q-1)/2-rp+p}{p} \neq 0$

by Lucas' theorem, this gives that $g_{(q-1)/2-(r-1)p} \neq 0$ identically, hence by the definition of I_2, we have $(q-1)/2-(r-1)p \geq I_2 > (q-p)/2$. This is only possible for $r=1$. $\square$

The above theorem implies in particular, that to prove Theorem 1.3 or even its generalization to an arbitrary odd prime power q (which is not a prime), one can suppose that the set U is the graph of a polynomial of degree $\frac{q+1}{2}$.

4. Proof of Theorem 1.3

From now on suppose $q=p^2$ for a prime p. For $p=2$ and $p=3$ there is nothing to prove, so suppose $p \geq 5$. By Theorem 3.8 let $f(x) = x^{\frac{q+1}{2}} + ... + c_0$ be a polynomial with $\frac{q+3}{2} \leq N(f) \leq \frac{q+p}{2}$ and $I_1 = I_2 = \frac{q-1}{2}$. We make a transformation to achieve $c_{\frac{q-1}{2}} = c_1 = c_0 = 0$. It is not difficult to see that this does not affect I_1 or I_2. We have to prove that f is equivalent to $x^{\frac{q+1}{2}}$.

The proof will be carried out in several steps.

Claim 1. Consider the intervals $A_i = (\frac{q-1}{2} - (i+1)p, \frac{q-1}{2} - ip]$ for $i = 0, 1, ..., \frac{p-3}{2}$. The only possible indices $j \in A_i$ with $c_j \neq 0$ are $\frac{q-1}{2} - ip, \frac{q-1}{2} - ip - 1, ..., \frac{q-1}{2} - ip - (i-1)$ (for $i=0$ this means that for all $j \in (\frac{q-1}{2} - p, \frac{q-1}{2}]$, $c_j = 0$).

Proof. We use Corollary 3.7 (ii). Here $q + 1 - I_1 = \frac{q+3}{2}$.

Using that in f^2 the coefficients of $x^{q-1}, ..., x^{q-p+1}$ are zero, we find that $c_{\frac{q-3}{2}} = ... = c_{(q-1)/2-p+1} = 0$. Then using the fact that in f^2 there is no $x^{q-p-1}, ..., x^{q-2p+1}$, we find that $c_{(q-1)/2-p-1} = ... = c_{(q-1)/2-2p+1} = 0$. Again we cannot cancel $c_{(q-1)/2-2p}$, but also $c_{(q-1)/2-2p-1}$. The reason for the latter is that in f^2 the terms $x^{\frac{q+1}{2}} x^{(q-1)/2-2p-1}$ and $(x^{(q-1)/2-p})^2$ give terms of the same degree, so they might cancel each other.

In general we use induction on i. Suppose we have proved the statement for $0, ..., i-1$ but $c_{(q-1)/2-ip-j} \neq 0$ for a $j \geq i$. Considering f^2 again, we find a term of degree $q - ip - j$. This is a contradiction unless we can have this term from the product of two terms of the form $(q-1)/2 - i_1 p - j_1$ and $(q-1)/2 - i_2 p - j_2$ for some $i_1, i_2 \leq i-1$ and $j_1 \leq i_1 - 1$, $j_2 \leq i_2 - 1$ (by the induction hypothesis). An easy calculation shows that this is not possible. $\square$

Note that what we have proved implies in particular, that all terms below $\frac{q+1}{2}$ have degree between 0 and $\frac{p-1}{2}$ modulo p.

Claim 2. If $f(x) \neq x^{\frac{q+1}{2}}$, then $f(x) = x^{\frac{q+1}{2}} + c_{(q-1)/2-jp} x^{(q-1)/2-jp} + ...$ with $c_{(q-1)/2-jp} \neq 0$. (That is, the first term after $\frac{q+1}{2}$ with nonzero coefficient has to be congruent to $\frac{p-1}{2}$ modulo p.)

Proof. Let $f(x) = x^{\frac{q+1}{2}} + c_s x^s + ...$ Then in the reduced form of $f(x)^2$ the coefficient of the term $x^{(q+1)/2+s}$ is not zero, hence by Corollary 3.7 (ii), $\frac{q+1}{2} + s$ is divisible by p.

Claim 3. If $f(x) \neq x^{\frac{q+1}{2}}$, then $f(x) = x^{\frac{q+1}{2}} + c_{(q-1)/2-p} x^{(q-1)/2-p} + ...$ with $c_{(q-1)/2-p} \neq 0$ (hence $j=1$ in the previous claim) and $c^p_{(q-1)/2-p} + c_{(q-1)/2-p} = 0$.

Proof. By the remark after Claim 1. one can show that after reduction $f(x)^p = x^{(q-1)/2+p} + c^p_{(q-1)/2-jp}x^{(q-1)/2-j} + ...$ Multiplying f and the reduced form of f^p we find that in the reduced form of f^{p+1} there are two big terms: $c^p_{(q-1)/2-jp}x^{q-j}$ and $c_{(q-1)/2-jp}x^{q-1-(j-1)p}$. These can cancel each other if $j = 1$ and $c^p_{(q-1)/2-jp} + c_{(q-1)/2-jp} = 0$, in all other cases f^{p+1} has a non-zero term of degree $q-j$. But this cannot happen, since this would mean that g_{p+j} is not zero identically (note that $\binom{p+j}{p+1}$ is not zero for $j \geq 1$).

Claim 4. $f(x) = x^{\frac{q+1}{2}}$.

Proof. Suppose $f(x) \neq x^{\frac{q+1}{2}}$. We summarize what we have from the previous three claims:

$$f(x) = x^{(q+1)/2} + c_{(q-1)/2-p}x^{(q-1)/2-p} + ...;$$

$$f(x)^p = x^{(q+1)/2+p-1} + c^p_{(q-1)/2-p}x^{(q-3)/2} + ...;$$

$$c^p_{(q-1)/2-p} + c_{(q-1)/2-p} = 0 \qquad (3).$$

Now consider $x^2(x^{p-1}f(x) - f(x)^p)^2$. This polynomial is the linear combination of polynomials of the form $x^k f(x)^l$ with $\binom{k+l}{k} \neq 0$, hence by the definition of I_2, after reduction it cannot have a term of degree $q-1$ (unless $2p+2 \geq I_1$). It is easy to see that this gives $c^p_{(q-1)/2-p} - c_{(q-1)/2-p} = 0$, which together with (3) implies $c_{(q-1)/2-p} = 0$, a contradiction.

So the proof is finished except for the case $2p+2 \geq I_1 = \frac{q-1}{2}$, this can only happen for $p = 5$. This case can be ruled out by computer. □
